COG Learning Theory

By Katie Pelkey

Definition of Learning: A relatively permanent change in mental representations or associations due to experience.

Mechanism of Learning: Building connections in the **schema** through the processes of **assimilation** and **accommodation**.

Assumptions: New information is related to previously-learned information; is not always behavioral though inferences are made from behavior; some learning processes are unique to humans.

Ex: Assimilation...the experience of petting the rabbit matches with what the learner knows about rabbits: they're soft and gentile.

Ex: Accommodation...the experience does not match what the speaker expected. The schema changes to account for this.

Vocabulary and Key Principles

- 1. **Schema:** A mental unit that summarizes an event
- **2. Assimilation:** Interaction with an object/event in a way that matches existing schema.
- 3. Accommodation: individual changes or forms new schema forms to account for a new event.
- **4. Short Term/Working Memory:** Information processed < 1 minute.
- **5.** Long-Term Memory: Information processed > 1 minute.

Theorists & their key contributions:

Jean Piaget: Proposed <u>4 cognitive stages of child</u> <u>development</u>

Lev Vygotsky: Coined the <u>socio-cultural theory</u> that children learn through interactions with adults and culture

Alan Baddeley: Proposed the <u>phonological loop</u> (auditory information lasts only a few seconds if not rehearsed) and model of working memory

Benjamin Bloom: Created hierarchy for <u>organizing</u> <u>educational goals</u>
